0 Executive Summary

Four discharge measurement campaigns have been conducted between 30 April and 25 May 2012. The results of the first two campaigns were documented in the Advisory Service Document No. 1, submitted on 21 May 2012. In order to give timely advice to the Lebanese Government all results obtained between 20 May and 02 June 2012 are documented in Addendum No. 1. More Addenda will follow when more results of importance for the proposed Janneh dam become available.

The aim of the discharge measurement campaigns 3 and 4 were to

- a) confirm the results of the first two tests;
- b) try to access the infiltration zone and narrow down its exact location and extent.

Tests 3 and 4 confirmed the results of the first two tests.

The results of all four discharge measurement campaigns are:

Date	Rouaiss [m ³ /s]	Afqa [m ³ /s]	Afqa+Rouaiss [m ³ /s]	Yanouh [m ³ /s]	infiltration [m ³ /s]	infiltration [%]
4/30/2012	47.0	26.7	73.7	40.3	33.4	45.3
5/16/2012	21.6	22.7	44.3	28.8	15.5	35.0
5/22/2012	12.1	17.4	29.5	14.3	15.2	51.5
5/25/2012	10.7	15.0	25.7	14.0	11.7	45.5

All four tests prove that a massive infiltration into the J4 aquifer exists in the Upper Nahr Ibrahim Valley. Infiltration varied between 35 % and 52 %. The main infiltration zone was identified but infiltration may also exist elsewhere. Further tests are needed and will be conducted by BGR.

The extent of the infiltration zone could be narrowed down slightly to the zone shown in Figure 23.

The lowest elevation of the assumed infiltration zone could be at approx. 800 m asl. There is a prominent cave at this location which is assumed to reach the valley bottom. **In any case the minimum storage level of the proposed Janneh dam of 834 m asl could most certainly never be reached. Janneh dam would act as an artificial recharge dam for Jeita spring.** It will be tried to access the infiltration zone during low flow.

In view of the current findings, it is strongly recommended not to go ahead with the construction of the planned Janneh dam.

In view of the current findings, it would not make sense to go ahead with the construction of the planned Janneh dam.

The infiltrating water is believed to flow towards Jeita spring, constituting a large share of discharge at Jeita spring. Any interference at the infiltration zone would directly affect Jeita spring. Should it be

Quantification of Infiltration Valley into the J4 Aquifer in the Upper Nahr Ibrahim Valley – Addendum No. 1

attempted to seal the infiltration zone, though practically impossible, discharge at Jeita spring would be significantly reduced.

It is of utmost importance to conduct the tracer test proposed to WEBML and Khatib and Alami in a borehole at Saraita, to be drilled by WEBML. A related request was submitted to WEBML and Khatib and Alami on 22 May 2012.

Quantification of Infiltration Valley into the J4 Aquifer in the Upper Nahr Ibrahim Valley – Addendum No. 1

1 Investigation Area

The assumed groundwater contribution zone of Jeita spring is shown in Figure 1 (MARGANE et al., in progr.).

During the first two measurements the infiltration could be narrowed down to an area between around 3,800 m upstream of the proposed Janneh dam going up for around 1 km (Figures 2 and 3).

2 Hydrological Setup

The data collection during the previous reporting had not been complete because until recently this area of Nahr Ibrahim had widely not been believed to be part of the Jeita catchment. The LRA monitoring station Rouaiss spring could previously not be located. Now related data were acquired and the station visited. The previously documented discharge measurements for Afqa are corrected in this report.

Average monthly discharge of Afqa spring (LRA station 21) during the water years 2000/01 - 2009-10 (Figures 6, 8, 9) indicate that peak flow is commonly during March to May. Average annual discharge during that period is 123 MCM (Table 1). At the Rouaiss spring station (Figures 7, 8, 10) average annual discharge is 154 MCM. The comparison of Afqa and Rouaiss discharge shows some very odd differences (Figure 8). In some years discharge at Afqa was higher than at Rouaiss, in other years it was inverse. Discharge at Rouaiss varies between 76 and 239 % of the Afqa discharge. The monthly discharge pattern is nearly the same at both stations (Figure 11).

Rouaiss spring is also monitored by LRA, however, at an inappropriate location (Figure 5), which is why the station was previously not found. The LRA station is located approx. 1.4 km downstream of Rouaiss spring at the Majdel bridge. However, about 740 m downstream of Rouaiss spring a considerable inflow of surface water takes place from the high plateau NW of Akoura (1800-2000 m asl). The LRA station is therefore not representative of the groundwater discharge at Rouaiss spring but is a combined measurement of groundwater (Rouaiss spring *sensu strictu*) and surface water (one part of the Rouaiss surface water catchment; Figure 5). A second major inflow to the Rouaiss branch of Nahr Ibrahim from the Laqlouq area (second part of the Rouaiss surface water catchment) is located approx. 1.8 km downstream of Rouaiss spring (or 400 m downstream of the LRA monitoring station). Those two surface water inflows bring a large amount of surface water to the Rouaiss branch as was observed during the snow melt in April/May 2012, however, cease quickly at the end of the snowmelt period.

It is recommended to establish a new station for Rouaiss spring discharge at the spring itself.

The measurements at the current LRA stations Rouaiss and Afqa do, for the above reasons, and furthermore due to the infiltration at the confluence of the Rouaiss and Afqa branches, not provide correct values for the amount of runoff at the proposed Janneh dam. Using a virtual station at Janneh dam, as was done in the hydrological report for Janneh dam, is not correct because groundwater - surface water interactions are not taken into account and because groundwater and surface water catchments do not match.

Moreover the only other downstream surface water monitoring station at the sea mouth of Nahr Ibrahim cannot be used for comparison because surface

Quantification of Infiltration Valley into the J4 Aquifer in the Upper Nahr Ibrahim Valley – Addendum No. 1

water and groundwater catchments are completely different (Figure 4). The Jeita groundwater catchment covers around 60 % of the Nahr Ibrahim surface water catchment (329 km²). Around 49 % of the Jeita groundwater catchment lies within the Nahr Ibrahim surface water catchment. However, not all of the surface water runoff in the Nahr Ibrahim catchment contributes to Jeita spring but only that portion which can infiltrate at specific locations where such infiltration can take place. This is the case at the confluence of the Rouaiss and Afqa branches of Nahr Ibrahim where a significant karst network has developed in the uppermost part at the J4 due to very intensive karstification (MARGANE et al., in progr.).

3 Description of Discharge Measurements

In order to confirm the assumed infiltration of surface water in the Upper Nahr Ibrahim Valley, four campaigns of discharge measurements were done:

- first discharge measurements: 30 April 2012
- second discharge measurements: 15 May 2012
- third discharge measurements: 22 May 2012
- fourth discharge measurements: 25 May 2012

While discharge in the Rouaiss branch of Nahr Ibrahim quickly decreased, recession at the Afqa branch was less (Figure 22).

3.1 Locations of Measurements

The first two measurement campaigns were intended to identify the assumed infiltration zone between the beginning of the J4 outcrop and the Janneh bridge. It became clear that infiltration in the Janneh area itself is small and the infiltration zone could be confined to the area near the confluence of the Rouaiss and Afqa branches. For the next two measurement campaigns measurements at the stations Afqa, Rouaiss and Yanouh/Joe Marine were repeated so that now four measurement campaigns with three identical reference stations are available. During the fourth measurement it was tried to carry out a measurement some 900 m upstream of Yanouh/Joe Marine, however, the distance between injection and monitoring was insufficient (95 m) so that this measurement is not correct. This is confirmed by the monitoring of tracer arrival from later injections at Rouaiss and Afqa. All stations used for monitoring and injection are shown in Tables 3 and 4.

Total distance between Afqa injection and Yanouh monitoring was approx. 3150 m, between Rouaiss injection and Yanouh monitoring approx. 2700 m.

The proposed dam location is at:

LONG (E)	LAT (N)	Elevation
35.836165°	34.081298°	755 m asl

The center of the assumed infiltration zone is at:

LONG (E)	LAT (N)	Elevation
35.876575°	34.089035°	~ 810 m asl

4 Tracer Tests

Accuracy of measurements is assumed to be 10-15 % during the first and 5-10 % during the second, third and fourth campaign.

4.1 Third Campaign

The third discharge measurements were conducted on 22 May 2012. At this time flow at Rouaiss and Afqa springs was much less than during the first two measurements due to receding snowmelt arriving via surface water in the Rouaiss branch. This recession in the Rouaiss branch can clearly be traced (Figure 22).

Figure 12: Locations of Injection and Monitoring during Third Measurement Campaign

The following injections were conducted (three at each station):

<i>Rouaiss + Afqa</i>			<i>29.5</i>

Table 6: Infiltration Measured during Third Campaign

Segment	Infiltration (m ³ /s)	Infiltration (%)
Confluence - Yanouh	15.2	52

All measurements were conducted using fluorometer 533. At each station a back-up measurement with a second fluorometer was carried out to avoid loss of data.

The tracer arrival from the Rouaiss and Afqa injections was also observed downstream at Yanouh.

Injections were done starting downstream and going up in the catchment. Time interval between injections at one station was usually 15 minutes. In order to be able to separate upstream injections at downstream monitoring sites, commonly between one and two hours had to elapse before starting injections at the next station.

There are no surface water inflows between the three stations.

4.2 Fourth Campaign

The fourth discharge measurements were conducted on 25 May 2012 in the presence of Kathib and Alami staff (consultant for Janneh dam).

During the field visit the consultant was shown:

- the presence of strong karstification in the upper J4 (it is not mentioned in the K+A reports)
- the presence of caves and thus a well developed karst network (it is not mentioned in the K+A reports)
- that there is only limestone and no dolomite (geological map of K+A is thus wrong)

<i>Rouaiss + Afqa</i>			<i>25.7</i>

Table 8: Infiltration Measured during Fourth Campaign

Segment	Infiltration (m ³ /s)	Infiltration (%)
Confluence - Yanouh	11.7	46

All measurements at the three reference stations were conducted with the same instrument (532). The arriving tracer was observed in all downstream stations by other instruments in order to observe tracer recovery and travel times between stations. In all stations the same amount of tracer (50 g) was used in order to make results easily comparable.

The arrival of tracer at Rouaiss-2 from the Rouaiss injections yields a discharge of 9.9 m³/s, i.e. 0.8 m³/s less than at Rouaiss. This indicates that already in this upper part of the J4 there could be some infiltration (7%). The monitoring of tracer arrival from the Rouaiss and Afqa injections at Yanouh-2 shows a clear difference. While only 38% of the tracer from the Rouaiss injection is lost, 47% of the tracer is lost on the way from Afqa to Yanouh-2. There may thus be a higher infiltration on the Afqa branch compared to the Rouaiss branch. The calculated discharge at Yanouh-2 is 13.5 m³/s, i.e. almost the same as the discharge determined directly at Yanouh.

Injections were done starting downstream and going up in the catchment. Time interval between injections at one station was commonly 10 to 15 minutes. In order to be able to separate upstream injections at downstream monitoring sites, commonly between one and two hours had to elapse before starting injections at the next station.

4.3 Results

The discharge measurements conducted by the BGR project show that **a very significant infiltration into the Lower Aquifer (J4, Keserwan Formation) occurred during all four campaigns in the Upper Nahr Ibrahim Valley. Infiltration varied between around 35 % and 52 %** (Table 9).

The infiltration zone could be narrowed down slightly to the area between Rouaiss-2, Afqa and Yanouh-2 (Figure 23). Monitoring at Yanouh-2, approx. 900 m upstream of the station Yanouh/Joe Marine, after the injections at the stations Afqa and Rouaiss, shows that infiltration must occur mainly upstream of this new station. Monitoring at the new station Rouaiss-2 after the injection at the station Rouaiss shows that there is a small infiltration between those two stations (7%) but the main infiltration must occur between Rouaiss-2, Afqa and Yanouh-2. The infiltration zone thus stretches over approx. 500 m along Nahr Ibrahim and its two tributaries.

Further measurements are required during periods of lower flow. The BGR project intends to conduct at least two more discharge monitoring campaigns for this purpose. It will also be tried to access the infiltration zone during the dry season.

The measurements show clearly that infiltration is varying with time. The reason may be that with higher water levels other parts of the karst network become connected where no infiltration takes place during low flow because their elevation is too high.

It is of utmost importance to conduct the tracer test proposed to WEBML and Khatib and Alami as discussed during the meeting on 21 May 2012 at WEBML and requested by BGR on 22 May 2012 (Annex-1). It was agreed that this borehole would be drilled by WEBML.

The infiltration zone could start at an elevation of approx. 800 m asl going up to around 860 m asl. The major infiltration is assumed to be at an elevation of 810-820 m asl. If a dam is built in this area it would continuously leak large quantities of water into the underlying karst network. Therefore the intended purpose of the Janneh dam, storage, could not be met.

This infiltrating water is believed to flow towards Jeita spring, constituting a large share of discharge at Jeita spring. Any interference at the infiltration zone would directly affect Jeita spring.

Accuracy of effected discharge measurements was around 10-15 % during the first campaign and 5-10 % during the second, third and fourth campaign.

There was no surface water inflow between the monitored stations during the third and fourth campaign.

Quantification of Infiltration Valley into the J4 Aquifer in the Upper Nahr Ibrahim Valley – Addendum No. 1

Table 9: Infiltration Rates determined during the four Measurement Campaigns

Date	Rouaiss [m ³ /s]	Afqa [m ³ /s]	Afqa+Rouaiss [m ³ /s]	Yanouh [m ³ /s]	infiltration [m ³ /s]	infiltration [%]
4/30/2012	47.0	26.7	73.7	40.3	33.4	45.3
5/16/2012	21.6	22.7	44.3	28.8	15.5	35.0
5/22/2012	12.1	17.4	29.5	14.3	15.2	51.5
5/25/2012	10.7	15.0	25.7	14.0	11.7	45.5

Infiltration means: amount of surface water runoff being lost between the stations Rouaiss / Afqa and Yanouh-2/Joe Marine. In order to make all measurements comparable, these will be used as reference stations in all consecutive reports.

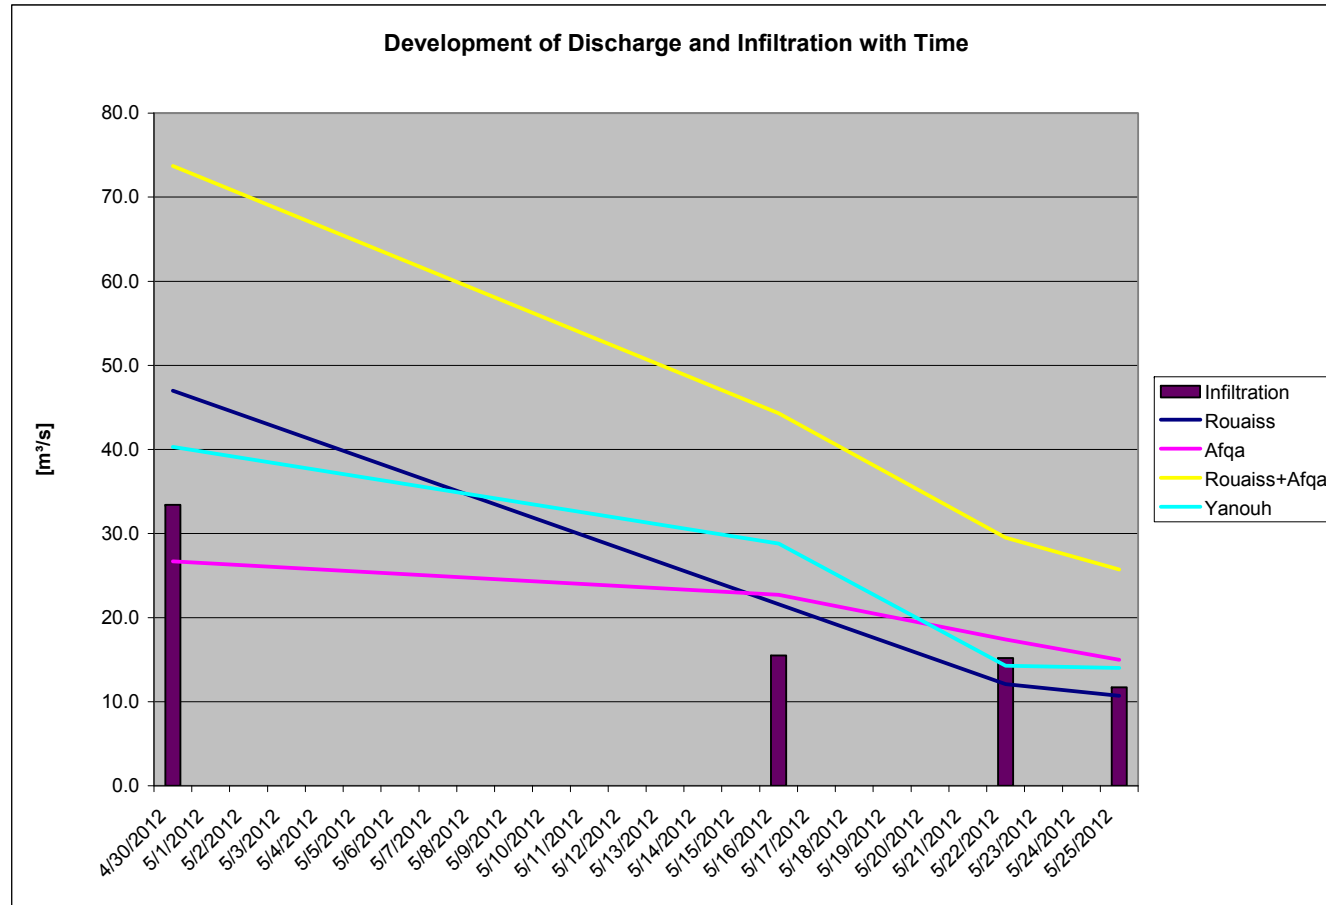

Figure 22: Development of Discharge and Infiltration during the four Measurements Campaigns

5 Conclusions and Recommendations

The results of all four measurement campaigns prove the existence of a massive infiltration into the J4 aquifer in the Upper Nahr Ibrahim Valley and have mayor implications for the currently ongoing planning of the Janneh dam which extends well into the assumed zone of high infiltration.

The exact location of the infiltration zone could be narrowed down to the area shown in Figure 23. **The infiltration zone could start at an elevation of approx. 800 m asl going up to around 860 m asl. The major infiltration is assumed to be at an elevation of 810-820 m asl.** The planned minimum level of the Janneh dam would be at 834 m asl, the maximum level at 839 m asl. Due to the infiltration between 14 and 29 m of storage would be lost completely.

In view of the current findings, it is strongly recommended not to go ahead with the construction of the planned Janneh dam.

The infiltrating water is believed to flow towards Jeita spring, constituting a large share of discharge at Jeita spring. Any interference at the infiltration zone would directly affect Jeita spring. Should it be attempted to seal the infiltration zone, though practically impossible, discharge at Jeita spring would be significantly reduced.

It is of utmost importance to conduct the tracer test proposed to WEBML and Khatib and Alami in a borehole at Saraita, to be drilled by WEBML. A related request was submitted to WEBML and Khatib and Alami on 22 May 2012.

It is recommended to establish a completely new monitoring of spring flow at Afqa and Rouaiss springs because both stations are in a state of disrepair and do not produce useful results. Construction costs for both are in the range of 1 Mio USD.
